#### Abstract

A Projected-Gradient Underdetermined Newton-like algorithm will be introduced for finding a solution of a Horizontal Nonlinear Complementarity Problem (HNCP) corresponding to a feasible solution of a Mathematical Programming Problem with Complementarity Constraints (MPCC). The algorithm employs a combination of Interior-Point Newton-like and Projected-Gradient directions with a line-search procedure that guarantees global convergence to a solution of HNCP or, at least, a stationary point of the natural merit function associated to this problem. Fast local convergence will be established under reasonable assumptions. The new algorithm can be applied to the computation of a feasible solution of MPCC with a target objective function value. Computational experience on test problems from well-known sources will illustrate the efficiency of the algorithm to find feasible solutions of MPCC in practice.

Keywords: Global optimization, Nonlinear programming, Nonlinear Systems of Equations, Complementarity Problems, Mathematical Programming with

[^0]Complementarity Constraints.

## 1. Introduction

A Mathematical Programming Problem with Complementarity Constraints (MPCC) [34, 36, 38] can be defined in the form

$$
\begin{equation*}
\text { Minimize } \varphi(x, y, w) \text { subject to } H(x, y, w)=0 \text { and } \min \{x, w\}=0 \tag{1}
\end{equation*}
$$

where $x, w \in \mathbb{R}^{n}, y \in \mathbb{R}^{m}$, while $\varphi: \mathbb{R}^{2 n+m} \rightarrow \mathbb{R}$, and $H: \mathbb{R}^{2 n+m} \rightarrow \mathbb{R}^{r}$ are continuously differentiable functions. The feasible set of MPCC will be denoted by $D$ and $\min \{x, w\}$ denotes a vector of components $\min \left\{x_{i}, w_{i}\right\}, i=1, \ldots, n$. For all $i=1, \ldots, n$, the variables $x_{i}, w_{i}$ are said to be complementary and satisfy:

$$
\begin{equation*}
x_{i} \geqslant 0, w_{i} \geqslant 0, x_{i} w_{i}=0, i=1, \ldots, n \tag{2}
\end{equation*}
$$

MPCC has appeared frequently in optimization models and has significant applications in different areas of science, engineering and economics 34, 36, 38, Many theoretical and application papers in Operations Research, as well as survey papers on related topics [7, 8, [25, 28, 32], have been devoted to this problem in recent years. For example, transport network models were considered in [17, 42, 43], bilevel optimization in [28], variational inequality formulations in 41, multiobjective problems with complementarity constraints in [33, 46, electricity markets in [10, 19, 22, 45], quadratic programming with complemen-
10 tarity constraints in 39, optimality conditions in 37, order-value applications in [1], and oligopolistic equilibrium in [44], among others.

Clearly, MPCC can be seen as a Nonlinear Programming Problem where the $n$ complementarity constraints $\min \left\{x_{i}, w_{i}\right\}=0$ are replaced with (2) or even with $x^{\top} w=0, x \geqslant 0, w \geqslant 0$. Attempts for solving MPCC by means of nonlinear programming algorithms present some difficulties, mainly because these algorithms may converge to points from which there exist obvious firstorder descent directions. This issue is a consequence of the so-called double
zeros or biactive indices, i.e., feasible points satisfying at least a constraint $x_{i} w_{i}=0$ with both variables $x_{i}$ and $w_{i}$ equal to zero. These difficulties have 20 motivated much research on weak forms of stationarity [13, 20, 34, 36, 38, 40, and several algorithms have been designed to compute such weak stationary points [4, 5, 6, 11, 14, 15, 16, 20, 23, 24, 26, 30, 34, 36, 38].

In this paper, we will discuss how to compute a feasible solution of the MPCC, that is, a solution of the following Horizontal 18 (possibly nonlinear) Complementarity Problem (HNCP):

$$
\left[\begin{array}{c}
H(x, y, w)  \tag{3}\\
x_{1} w_{1} \\
\vdots \\
x_{n} w_{n}
\end{array}\right]=0, x \geq 0, w \geq 0
$$

We will assume that $r \leq m+n$, so that the number of equations in (3) is smaller than or equal to the number of unknowns. The case in which $r=m+n$ 25 has been studied in [3]. The case of $H$ affine has been thoroughly discussed in the literature (see for instance [25] for a recent survey). The HNCP is NPhard in this case 35] but there are many MPCCs where finding a single feasible solution can be considered as an easy task [25].

The problem of finding a feasible point of MPCC at which the objective function achieves a target value $c_{t}$ is naturally formulated as follows:

$$
\begin{equation*}
\varphi(x, y, w) \leqslant c_{t}, H(x, y, w)=0, x \geqslant 0, w \geqslant 0 \text { and } x^{\top} w=0 \tag{4}
\end{equation*}
$$

Note that the problem (4) can be written as a standard HNCP adding two auxiliary variables $v_{1}$ and $v_{2}$, as follows:

$$
\begin{gather*}
\varphi(x, y, w)+v_{1}=c_{t}, H(x, y, w)=0, v_{1} v_{2}=0, x_{i} w_{i}=0, i=1, \ldots, n  \tag{5}\\
v_{1} \geq 0, v_{2} \geq 0, x \geq 0, \text { and } w \geq 0
\end{gather*}
$$

In this paper we will extend the algorithm introduced in [3], which deals with

30 the case $r=n+m$, for the underdetermined HNCP (3) where $r$ may be smaller than $n+m$. The Projected-Gradient Underdetermined Newton-like algorithm (PGUN) combines fast interior-point iterations with projected-gradient steps. A line-search procedure is employed guaranteeing sufficiently reduction of the natural merit function [2] associated to HNCP. This will allow us to establish

35 global convergence of the PGUN algorithm to a solution of HNCP or to a stationary point of the merit function with a positive function value. In this case the algorithm terminates unsuccessfully. Fast local convergence will be established under reasonable hypotheses.

Computational experience with PGUN for solving the HNCP associated to [29] will show that, for many instances, projected-gradient iterations are seldom used and the algorithm is able to converge very fast to a solution of HNCP. For other instances, PGUN converges slowly using projected-gradient iterations to a stationary point of the merit function that seems not to be a solution of 45 the HNCP. A practical criterion will be introduced to stop prematurely PGUN and avoid many projected-gradient iterations. As the natural merit function is nonconvex, the choice of the starting point is very important for the success of PGUN. Here we will suggest to restart the PGUN algorithm with a new initial point whenever the criterion mentioned before forced the algorithm to stop prematurely. Numerical results with an implementation of PGUN incorporating these two practical procedures (premature stopping criterion and restarting) show that the method is in general efficient to solve the HNCP and seems to perform better than a Projected Levenberg-Marquardt algorithm [27]. We have also tested PGUN for solving (5) associated to a target $c_{t}$ equal to the best before. As discussed in [12], the introduction of the target constraint to HNCP makes this problem more difficult to tackle and PGUN has more difficulties to solve the HNCP in this case. Despite this, PGUN has been able to provide a target feasible solution of MPCC for the large majority of tested instances.

The organization of this paper is as follows. The properties of the merit
function for the HNCP are studied in Section 2. The algorithm PGUN will be described and its global convergence will be analyzed in Section 3. Section 4 will be devoted to the local convergence of the PGUN algorithm. Computational experience with the PGUN algorithm will be reported in Section 5 and some ${ }_{65}$ conclusions will be presented in the last section of the paper.

Notation: The 2-norm of vectors and matrices will be denoted by $\|\cdot\|$. If there is no risk of confusion we denote $(x, y, w)=\left(x^{\top}, y^{\top}, w^{\top}\right)^{\top}$, as it has been already done in the Introduction. We adopt the usual convention of denoting $X$ the diagonal matrix whose entries are the elements of $x \in \mathbb{R}^{n}$. The MoorePenrose pseudoinverse of the matrix $A$ will be denoted by $A^{\dagger}$. The Jacobian matrix of $\Phi: \mathbb{R}^{n} \rightarrow \mathbb{R}^{m}$, with components $\varphi_{1}, \ldots, \varphi_{m}$, will be defined by

$$
\Phi^{\prime}(z)=\left[\begin{array}{ccc}
\frac{\partial \varphi_{1}}{\partial z_{1}}(z) & \ldots & \frac{\partial \varphi_{1}}{\partial z_{n}}(z) \\
\vdots & \ddots & \vdots \\
\frac{\partial \varphi_{m}}{\partial z_{1}}(z) & \ldots & \frac{\partial \varphi_{m}}{\partial z_{n}}(z)
\end{array}\right]
$$

We define $e=(1, \ldots, 1)^{\top}$ and

$$
\begin{equation*}
\Omega=\{(x, y, w): x \geqslant 0, w \geqslant 0\} . \tag{6}
\end{equation*}
$$

The Interior of this set will be denoted by $\operatorname{Int}(\Omega)$.

## 2. Stationary points of the sum of squares

The HNCP (3) may be expressed in the form

$$
\begin{equation*}
F(x, y, w)=0, x \geq 0, w \geq 0 \tag{7}
\end{equation*}
$$

where $F: \mathbb{R}^{n+m+n} \longrightarrow \mathbb{R}^{r+n}$ is given by

$$
F(x, y, w)=\left[\begin{array}{c}
H(x, y, w)  \tag{8}\\
x_{1} w_{1} \\
\vdots \\
x_{n} w_{n}
\end{array}\right]
$$

70 and $H: \mathbb{R}^{n+m+n} \rightarrow \mathbb{R}^{r}$ has continuous first derivatives.
We define the natural merit function:

$$
\begin{equation*}
f(x, y, w)=\|F(x, y, w)\|^{2} \tag{9}
\end{equation*}
$$

and we consider the problem

$$
\begin{equation*}
\text { Minimize } f(x, y, w) \text { subject to }(x, y, w) \in \Omega \tag{10}
\end{equation*}
$$

where $\Omega$ is defined in (6). From now on we will denote $z=(x, y, w)$.
It is well known that, if $z^{*}$ is an unconstrained stationary point of "Minimize $\|\Phi(z)\|^{2} "$ and the residual $\Phi\left(z^{*}\right)$ is not null, then the rows of the $\Phi^{\prime}\left(z^{*}\right)$ are linearly dependent. In general, this property is not true in the presence of
75 bound constraints. In what follows, generalizing a result proved in 2, we prove that the non-full-rank property also holds in the case of problem with the definitions (8) and (9).

Theorem 2.1. Suppose that $\bar{z}=(\bar{x}, \bar{y}, \bar{w}) \in \Omega$ is a stationary point of (10).
Then,
80 (a) if $H(\bar{z})=0$ or $H_{y}^{\prime}(\bar{z})$ is full row-rank, then $\bar{z}$ is solution of (7);
(b) if $\|F(\bar{z})\| \neq 0$, the rows of the Jacobian $F^{\prime}(\bar{z})$ are linearly dependent.

Proof. If $\bar{z}$ is a stationary point of 10 , then

$$
\begin{gather*}
\frac{1}{2} \nabla f(\bar{z})=F^{\prime}(\bar{z})^{\top} F(\bar{z})=\left[\begin{array}{cc}
H_{x}^{\prime}(\bar{z})^{\top} & W \\
H_{y}^{\prime}(\bar{z})^{\top} & 0 \\
H_{w}^{\prime}(\bar{z})^{\top} & X
\end{array}\right]\left[\begin{array}{c}
H(\bar{z}) \\
\overline{x_{1}} \overline{w_{1}} \\
\vdots \\
\overline{x_{n}} \overline{w_{n}}
\end{array}\right]=\left[\begin{array}{c}
\gamma \\
0 \\
\alpha
\end{array}\right],  \tag{11}\\
\overline{x_{i}} \gamma_{i}=0, \quad i=1, \ldots, n \\
\overline{w_{i}} \alpha_{i}=0, \quad i=1, \ldots, n  \tag{12}\\
\bar{x} \geq 0, \quad \gamma \geq 0, \quad \bar{w} \geq 0, \text { and } \alpha \geq 0 .
\end{gather*}
$$

(a) If $H(\bar{z})=0$, we deduce that:

$$
\left[\begin{array}{c}
W \\
X
\end{array}\right]\left[\begin{array}{c}
\overline{x_{1}} \overline{w_{1}} \\
\vdots \\
\overline{x_{n}} \overline{w_{n}}
\end{array}\right]=\left[\begin{array}{c}
\gamma \\
\alpha
\end{array}\right]
$$

Thus, $\bar{x}_{i} \bar{w}_{i}=0$ for all $i=1, \ldots, n$ and $\bar{z}$ is a solution of (7).
On the other hand, if $H_{y}^{\prime}(\bar{z})$ is full row-rank, then, by 11), $H(\bar{z})=0$. Therefore, as proved above, we have that $\bar{z}$ is solution of 7 .
(b) Suppose now that $F(\bar{z}) \neq 0$. By (11), if $\bar{x}_{i}=\bar{w}_{i}=0$ for some $i \in$ $\{1, \ldots, n\}$, the column $r+i$ of

$$
\left[\begin{array}{cc}
H_{x}^{\prime}(\bar{z})^{\top} & W \\
H_{y}^{\prime}(\bar{z})^{\top} & 0 \\
H_{w}^{\prime}(\bar{z})^{\top} & X
\end{array}\right]
$$

85
is null, Then the the rows of $F^{\prime}(\bar{z})$ are linearly dependent.
Assume that $\bar{x}_{i_{k}}>0$ and $\bar{w}_{i_{k}}>0$ for $q$ indices $i_{k}, k=1, \ldots, q$ belonging to $\{1, \ldots, n\}$. Then there are three possible cases:

Case 1: $q=n$;
Case 2: $q=0$;
Case 3: $1 \leq q<n$.

In Case 1 , the stationarity imposes that the derivatives of $f$ with respect to all the variables must vanish. Therefore,

$$
\left[\begin{array}{cc}
H_{x}^{\prime}(\bar{z})^{\top} & W \\
H_{y}^{\prime}(\bar{z})^{\top} & 0 \\
H_{w}^{\prime}(\bar{z})^{\top} & X
\end{array}\right]\left[\begin{array}{c}
H(\bar{z}) \\
\overline{x_{1}} \overline{w_{1}} \\
\vdots \\
\overline{x_{n}} \overline{w_{n}}
\end{array}\right]=0,
$$

with $\bar{x}_{i} \bar{w}_{i}>0$ for all $i=1, \ldots, n$. Then, the rows of $F^{\prime}(\bar{z})$ are linearly dependent.

Let us now consider Case 2. Since the case in which there exists $i$ such that $\bar{x}_{i}=\bar{w}_{i}=0$ has already been considered, we have that $\bar{x}_{i}+\bar{w}_{i}>0$ for all $i=1, \ldots, n$. Then, we may assume without loss of generality that $\bar{x}_{i}=0, \bar{w}_{i}>0$ for all $i=1, \ldots, n$. Then, by (11),

$$
\left[\begin{array}{cc}
H_{x}^{\prime}(\bar{z})^{\top} & \bar{W}  \tag{13}\\
H_{y}^{\prime}(\bar{z})^{\top} & 0 \\
H_{w}^{\prime}(\bar{z})^{\top} & 0
\end{array}\right]\left[\begin{array}{c}
H(\bar{z}) \\
0
\end{array}\right]-\left[\begin{array}{l}
\gamma \\
0 \\
0
\end{array}\right]=0
$$

Thus,

$$
\left[\begin{array}{cc}
H_{y}^{\prime}(\bar{z})^{\top} & 0 \\
H_{w}^{\prime}(\bar{z})^{\top} & 0
\end{array}\right]\left[\begin{array}{c}
H(\bar{z}) \\
0
\end{array}\right]=\left[\begin{array}{l}
0 \\
0
\end{array}\right] .
$$

This implies that the matrix

$$
\left[\begin{array}{ll}
H_{y}^{\prime}(\bar{z})^{\top} & 0 \\
H_{w}^{\prime}(\bar{z})^{\top} & 0
\end{array}\right]
$$

has at most $r-1$ linearly independent columns. Therefore, the matrix

$$
\left[\begin{array}{cc}
H_{x}^{\prime}(\bar{z})^{\top} & \bar{W} \\
H_{y}^{\prime}(\bar{z})^{\top} & 0 \\
H_{w}^{\prime}(\bar{z})^{\top} & 0
\end{array}\right]
$$

has at most $n+r-1$ linearly independent columns. Since $\bar{X}=0$, this implies that

$$
\left[\begin{array}{cc}
H_{x}^{\prime}(\bar{z})^{\top} & \bar{W} \\
H_{y}^{\prime}(\bar{z})^{\top} & 0 \\
H_{w}^{\prime}(\bar{z})^{\top} & \bar{X}
\end{array}\right]
$$

has at most $n+r-1$ linearly independent columns. Thus $F^{\prime}(\bar{z})$ has at most $n+r-1$ linearly independent rows. Since $F^{\prime}(\bar{z})$ has $n+r$ rows, it turns out
95 that this Jacobian is not full row-rank.
Let us now consider Case 3. Suppose, without loss of generality, that

$$
\begin{equation*}
\bar{x}_{i}, \bar{w}_{i}>0 \text { for } i=1, \ldots, q<n \tag{14}
\end{equation*}
$$

and

$$
\begin{equation*}
\bar{x}_{i}=0, \bar{w}_{i}>0 \text { for } i=q+1, \ldots, n . \tag{15}
\end{equation*}
$$

Splitting the first block of (11) into two blocks corresponding to its first $q$ and last $n-q$ equations, using 12,14 and 15 , calling $\widehat{H}_{x}^{\prime}(\bar{z})$ to the matrix formed by the first $q$ rows of $H_{x}^{\prime}(\bar{x}, \bar{y}, \bar{z})^{\top}$, and calling $\widehat{W}$ to the diagonal $q \times q$ matrices whose entries are $\bar{w}_{1}, \ldots, \bar{w}_{q}$, we obtain:

$$
\left[\begin{array}{cc}
\widehat{H}_{x}^{\prime}(\bar{z})^{\top} & \widehat{W}  \tag{16}\\
H_{y}^{\prime}(\bar{z})^{\top} & 0 \\
\bar{H}_{w}^{\prime}(\bar{z})^{\top} & \bar{X} \\
\tilde{H}_{w}^{\prime}(\bar{z})^{\top} & 0
\end{array}\right]\left[\begin{array}{c}
H(\bar{z}) \\
\overline{x_{1}} \overline{w_{1}} \\
\vdots \\
\overline{x_{q}} \overline{w_{q}}
\end{array}\right]=\left[\begin{array}{c}
0 \\
0 \\
0
\end{array}\right] .
$$

Therefore, the matrix

$$
A=\left[\begin{array}{cc}
\widehat{H}_{x}^{\prime}(\bar{z})^{\top} & \widehat{W} \\
H_{y}^{\prime}(\bar{z})^{\top} & 0 \\
\bar{H}_{w}^{\prime}(\bar{z})^{\top} & \bar{X} \\
\tilde{H}_{w}^{\prime}(\bar{z})^{\top} & 0
\end{array}\right]
$$

has at most $r+q-1$ linearly independent columns. Now define $\tilde{H}_{x}^{\prime}(\bar{z})^{\top}$ as the matrix containing the last $n-q$ rows of $H_{x}^{\prime}(\bar{z})^{\top}, \tilde{W}$ as the diagonal matrix
whose entries are $\bar{w}_{q+1}, \ldots, \bar{w}_{n}$, and

$$
B=\left[\begin{array}{ccc}
\widehat{H}_{x}^{\prime}(\bar{z})^{\top} & \widehat{W} & 0 \\
\tilde{H}_{x}^{\prime}(\bar{z})^{\top} & 0 & \tilde{W} \\
H_{y}^{\prime}(\bar{z})^{\top} & 0 & 0 \\
\bar{H}_{w}^{\prime}(\bar{z})^{\top} & \bar{X} & 0 \\
\tilde{H}_{w}^{\prime}(\bar{z})^{\top} & 0 & 0
\end{array}\right]
$$

Since $B$ comes from adding $n-q$ rows and columns to $A$, the matrix $B$ has at most $n+r-1$ linearly independent columns. But, by (11), 14), and (15), we have that $B=F^{\prime}(\bar{z})^{\top}$. Therefore, the Jacobian is not a full row-rank matrix, as we wanted to prove.

## 3. Projected gradient underdetermined Newton-like algorithm and global convergence

In this section we introduce a Projected Gradient Underdetermined Newtonlike (PGUN) Algorithm for the solution of the (possibly) underdetermined system (8). This algorithm is an extension of the method introduced in 3 for the solution of this system when the number of equalities is equal to the number of variables, i.e., when $r=n+m$. PGUN generates iterates lying inside $\operatorname{Int}(\Omega)$ and combines interior-point Newton-like and projected-gradient directions with a line-search procedure. The steps of the PGUN method are presented below.

## PGUN Algorithm

Step 0: Initial setup: Consider $\gamma>0$ and $\gamma_{k}>0$ for all $k \in \mathbb{N}$ and such that $\sum_{k=0}^{\infty} \gamma_{k}=\gamma<\infty$. Let $\tau \in(0,1), \sigma \in(0,1), 0<\bar{\eta}_{1}<\bar{\eta}_{2}, \rho>0$, $\beta \in\left(0, \frac{1}{2}\right), c_{\text {big }}>c_{\text {small }}>0, c_{\text {small }}<1$. Let $z^{0}=\left(x^{0}, y^{0}, w^{0}\right) \in \operatorname{Int}(\Omega)$. Assume that $z^{k}=\left(x^{k}, y^{k}, w^{k}\right) \in \operatorname{Int}(\Omega), \sigma_{k} \in[0,1 / 6], \tau_{k} \in[\tau, 1)$, and $\eta_{k} \in\left[\bar{\eta}_{1}, \bar{\eta}_{2}\right]$. Then, the steps for obtaining $z^{k+1}=\left(x^{k+1}, y^{k+1}, w^{k+1}\right) \in$ $\operatorname{Int}(\Omega)$ or declaring finite convergence are the following:

Step 1: Declare finite convergence if the scaled projected-gradient is zero: Compute $g\left(z^{k}, \eta_{k}\right)=P_{\Omega}\left(z^{k}-\eta_{k} \nabla f\left(z^{k}\right)\right)-z^{k}$. If $g\left(z^{k}, \eta_{k}\right)=0$, stop. (An approximate stationary point of 10 has been obtained.)

Step 2: Newton-like direction: Compute, if possible, $d^{k}=\left(d_{x}^{k}, d_{y}^{k}, d_{w}^{k}\right) \in \mathbb{R}^{n+m+n}$ satisfying

$$
\begin{equation*}
H^{\prime}\left(z^{k}\right) d^{k}+H\left(z^{k}\right)=0 \tag{17}
\end{equation*}
$$

and

$$
\begin{equation*}
x_{i}^{k} w_{i}^{k}+x_{i}^{k}\left(d_{w}^{k}\right)_{i}+w_{i}^{k}\left(d_{x}^{k}\right)_{i}=\mu_{i}^{k} \tag{18}
\end{equation*}
$$

where $\mu^{k} \geqslant 0$ and

$$
\begin{equation*}
\left\|\mu^{k}\right\|_{\infty} \leq \sigma_{k} \frac{\left(x^{k}\right)^{\top} w^{k}}{n} \tag{19}
\end{equation*}
$$

If such a direction $d^{k}$ does not exist or if $\left\|d^{k}\right\|>c_{\text {big }}$, go to Step 4 .
Step 3: Compute the maximum steplength: Compute

$$
\begin{equation*}
\alpha_{k}^{\text {break }}=\max \left\{\alpha \geq 0 \mid z^{k}+\alpha d^{k} \in \Omega\right\} \tag{20}
\end{equation*}
$$

and

$$
\begin{equation*}
\alpha_{k}^{\max }=\min \left\{1, \tau_{k} \alpha_{k}^{\text {break }}\right\} \tag{21}
\end{equation*}
$$

$$
\begin{equation*}
\left\|F\left(z^{k}+\alpha d^{k}\right)\right\| \leq\left\|F\left(z^{k}\right)\right\|-\rho\left\|\alpha d^{k}\right\|^{2}+\gamma_{k} \tag{22}
\end{equation*}
$$

set $\alpha_{k}=\alpha$ and go to Step 6.
Step 5.2: Choose $\alpha_{\text {new }} \in[\beta \alpha,(1-\beta) \alpha]$, set $\alpha=\alpha_{\text {new }}$ and go to Step 5.1.

Step 6: Compute the new iterate: Choose $z^{k+1} \in \Omega$ such that

$$
\begin{equation*}
\left\|F\left(z^{k+1}\right)\right\| \leq\left\|F\left(z^{k}+\alpha_{k} d^{k}\right)\right\| \tag{23}
\end{equation*}
$$

## End.

Given $z^{k}$ not satisying the stopping criterion $g\left(z^{k}, \eta_{k}\right)=0$, the fact that $z^{k+1}$ is well defined follows trivially from Step 5 , using $\gamma_{k}>0$. The global convergence of PGUN is established in Theorem 3.1.

Theorem 3.1. Given $z^{k}=\left(x^{k}, y^{k}, w^{k}\right)$ such that $x^{k}>0, w^{k}>0$ and $g\left(z^{k}, \eta_{k}\right) \neq$ $0)$, the point $\left(x^{k+1}, y^{k+1}, w^{k+1}\right) \in \operatorname{Int}(\Omega)$ is always well defined. Moreover, if $\left\{z^{k}\right\}$ is a sequence generated by Algorithm PGUN and $z^{*}$ is a cluster point such that $\lim _{k \in K_{1}} z^{k}=z^{*}$, where $K_{1} \subset I N$ is an infinite subsequence of indices, then:

1. $z^{*}$ is a stationary point of Minimize $f(z)$ subject to $z \in \Omega$.
2. If $F^{\prime}\left(z^{*}\right)$ is a full row-rank matrix, then $F\left(z^{*}\right)=0$.
3. If $K_{1}$ contains infinitely many indices $k$ such that $d^{k}$ is computed (at Step 2) as a Newton-like direction, then $F\left(z^{*}\right)=0$.

Proof. The stationarity of $z^{*}$ and the fact that $F\left(z^{*}\right)=0$ when $K_{1}$ contains infinitely many Newton-like iterations follow exactly as in 3, where the theorem was proved for the (square) case in which $n+m=r$. In the general case considered here the second part of the thesis is a consequence of the stationarity of $z^{*}$ and Theorem 2.1.

## 4. Local convergence

At Step 2 of PGUN one considers the linear system given by 17) and 18). If this linear system is incompatible the algorithm goes to Step 4 where a projected gradient direction is computed. All along this section we will assume that, whenever $17-18$ is compatible, the computed direction $d^{k}$ will be the
minimum-norm solution of that system. This implies that $d^{k}$ belongs to the range space of $F^{\prime}\left(z^{k}\right)^{\top}$ and

$$
d^{k}=F^{\prime}\left(z^{k}\right)^{\dagger}\left[\begin{array}{c}
-H\left(z^{k}\right)  \tag{24}\\
-X_{k} W_{k} e+\mu^{k}
\end{array}\right]
$$

where $\mu^{k} \geqslant 0$ satisfies 19 .
Note that the minimum-norm Newtonian direction associated with the system $F(z)=0$ would be obtained taking $\mu^{k}=0$ in 24 .

In Theorem 3.1 we proved that limit points of a sequence generated by PGUN are necessarily stationary points of the natural merit function $f$. Moreover, when the Jacobian of $F$ is full row-rank at a limit point, this point is a solution of the problem. Finally, every limit point of a subsequence of iterates $x^{k}$ such that $d^{k}$ is always computed at Step 2 is necessarily a solution of the nonlinear system. These global convergence results will be complemented in this section by local characterizations that tell us something about convergence of the whole sequence and its speed of convergence.

The local results that will be presented in this section are closely related with the local convergence results of Newton's method for underdetermined nonlinear systems. Roughly speaking, we are going to prove that, in a neighborhood of a solution at which the Jacobian has full row-rank, PGUN reduces to something very similar to Newton's method with the minimum norm choice of the solution of the linear system and, as a consequence, enjoys the local convergence properties of that method. However, the identification of the local PGUN and Newton's method in that case is not complete because $\mu^{k}$ may not be zero in (24).

Recall that PGUN does not admit negative components of $\left(x^{k}, w^{k}\right)$. Therefore, the search direction is multiplied by a factor $\alpha_{\max }^{k}$ that inhibits the possibility of taking a trial point with non-positive components in $(x, w)$. For proving that, eventually, PGUN behaves as a pure Newton-like method, we need to prove that $\alpha_{\max }^{k}$ is as close to 1 as desired. This essentially means that we
do not need to truncate the direction computed at (24). We will prove this property in Theorem 4.1. In Theorem 4.2 we will prove that, if the Jacobian has full row-rank at a limit point, the whole sequence converges to that limit point. As a by-product we will prove that, eventually, $\alpha_{k}=\alpha_{k}^{\max }$, which means that the first trial point at Step 5 of PGUN is accepted because the norm of $F$ decreases as required by 22 . The consequence of Theorems 4.1 and 4.2 is that, for $k$ large enough, PGUN is very similar to Newton's method with the Moore-Penrose pseudoinverse choice of linear-system solution. The fact that $\alpha_{k}=\alpha_{k}^{\text {max }}$, together with Theorem 4.1, implies that $\alpha_{k} \approx 1$. Therefore, the result of Theorem 4.3 (superlinear and quadratic convergence) is not surprising, since this is the type of result that is typically obtained for Newton's method in the underdetermined and regular case. Here we could invoke well-known results as the ones given by Chen and Yamamoto in [9] but we prefer include the complete proof for the sake of completeness.

### 4.1. Behaviour of the maximum steplength

In this section we aim to prove that, in a neighbourhood of a solution $z^{*}$ of (7) such that $F^{\prime}\left(z^{*}\right)$ is full row-rank, the steplength $\alpha_{k}^{\max }$, computed at Step 3 of PGUN (formulas 20 and 21 ), with $d^{k}$ computed at Step 2, can be taken as close to 1 as desired. This means that, given an arbitrary $\delta<1$, if $z^{k}$ is close enough to the solution, the maximal steplength $\alpha_{k}^{b r e a k}$ is bigger than $\delta$. This result has been proved in the case that $2 n+m=r+n$ (square system) in [3]. The proof in the rectangular case is more involved since the solution of the Newtonian linear system is not unique.

Theorem 4.1 Assume that Algorithm PGUN is applied to problem 7) and that $z^{*}$ is a solution at which the Jacobian $F^{\prime}\left(z^{*}\right)$ is full row-rank. Assume that $\delta \in(0,1)$. Then, there exists $\varepsilon>0$ such that, whenever $\left\|z^{k}-z^{*}\right\| \leq \varepsilon$ one has that $d^{k}$ is well defined by (17) and (18) and $\alpha_{k}^{\text {break }} \geq \delta$.

Proof. Assume that $F^{\prime}\left(z^{*}\right)$ is full row-rank and $F\left(z^{*}\right)=0$. Denote $W \in \mathbb{R}^{n \times n}$ the diagonal matrix whose entries are $w_{1}, \ldots, w_{n}$ and $X$ the diagonal matrix
whose entries are $x_{1}, \ldots, x_{n}$. Then,

$$
F^{\prime}(z)=\left[\begin{array}{ccc}
H_{x}^{\prime}(z) & H_{y}^{\prime}(z) & H_{w}^{\prime}(z) \\
W & 0 & X
\end{array}\right] \in \mathbb{R}^{(r+n) \times(2 n+m)}
$$

Since $F^{\prime}\left(z^{*}\right)$ is full row-rank, $x_{i}^{*}$ and $w_{i}^{*}$ can not be zero simultaneously. Without loss of generality (perhaps changing the names of some variables $x_{i}$ and $w_{i}$ ), we may assume that $x_{i}^{*}=0$ and $w_{i}^{*}>0$ for all $i=1, \ldots, n$. So,

$$
F^{\prime}\left(z^{*}\right)=\left[\begin{array}{ccc}
H_{x}^{\prime}\left(z^{*}\right) & H_{y}^{\prime}\left(z^{*}\right) & H_{w}^{\prime}\left(z^{*}\right) \\
W_{*} & 0 & 0
\end{array}\right]
$$

Therefore, by the linear independence of the rows of $F^{\prime}\left(z^{*}\right)$, the matrix $\left[H_{y}^{\prime}\left(z^{*}\right) \quad H_{w}^{\prime}\left(z^{*}\right)\right]$ is full row-rank.

Let $\varepsilon>0$ be such that, for all $z$ such that $\left\|z-z^{*}\right\| \leq \varepsilon$,

$$
\begin{equation*}
F^{\prime}(z) \text { and } H_{y w}^{\prime}(z) \equiv\left[H_{y}^{\prime}(z) \quad H_{w}^{\prime}(z)\right] \text { are full row-rank. } \tag{25}
\end{equation*}
$$

Since $H$ has continuous first derivatives, 25 implies that $\left\|F^{\prime}(z)^{\dagger}\right\|$ and $\left\|H_{y w}^{\prime}(z)^{\dagger}\right\|$ are uniformly bounded for all $z$ such that $\left\|z-z^{*}\right\| \leq \varepsilon$.

For a generic $z=(a, b, c), a>0, c>0$ such that $\left\|z-z^{*}\right\| \leq \varepsilon$, and $\mu \geqslant 0 \in \mathbb{R}^{n}$ we define $x, y$, and $w$ in such a way that $(x-a, y-b, w-c)$ is the minimum norm solution of:

$$
\left\{\begin{array}{l}
H_{x}^{\prime}(a, b, c)(x-a)+H_{y}^{\prime}(a, b, c)(y-b)+H_{w}^{\prime}(a, b, c)(w-c)=-H(a, b, c)  \tag{26}\\
C(x-a)+A(w-c)=-C a+\mu
\end{array}\right.
$$

Clearly, $x, y, w$ are functions of $a, b, c$, and $\mu$ but we do not make this dependence explicit in order to simplify the notation.

By the boundedness of $\left\|F^{\prime}(a, b, c)^{\dagger}\right\|$,

$$
\begin{equation*}
\lim _{(z, \mu) \rightarrow\left(z^{*}, 0\right)}\|x-a\|=\lim _{(z, \mu) \rightarrow\left(z^{*}, 0\right)}\|w-c\|=\lim _{(z, \mu) \rightarrow\left(z^{*}, 0\right)}\|y-b\|=0 \tag{27}
\end{equation*}
$$

So,

$$
\begin{equation*}
\lim _{(z, \mu) \rightarrow\left(z^{*}, 0\right)}(x, w)=\left(x^{*}, w^{*}\right)=\left(0, w^{*}\right) \tag{28}
\end{equation*}
$$

By (26) and simplifying the notation, we have that:

$$
\left[\begin{array}{ccc}
H_{x}^{\prime} & H_{y}^{\prime} & H_{w}^{\prime}  \tag{29}\\
C & 0 & A
\end{array}\right]\left[\begin{array}{c}
x-a \\
y-b \\
w-c
\end{array}\right]=\left[\begin{array}{c}
-H \\
-C a+\mu
\end{array}\right] \in \mathbb{R}^{r+n}
$$

Taking the minimum norm solution of 29, we have that $(x-a, y-b, w-c)^{\top}$ belongs to the range space of $F^{\prime}\left(z^{*}\right)^{\top}$. Therefore, there exist $q \in \mathbb{R}^{p}$ and $t \in \mathbb{R}^{n}$ such that

$$
\left[\begin{array}{c}
x-a  \tag{30}\\
y-b \\
w-c
\end{array}\right]=\left[\begin{array}{cc}
\left(H_{x}^{\prime}\right)^{\top} & C \\
\left(H_{y}^{\prime}\right)^{\top} & 0 \\
\left(H_{w}^{\prime}\right)^{\top} & A
\end{array}\right]\left[\begin{array}{c}
q \\
t
\end{array}\right] \in \mathbb{R}^{m+2 n}
$$

Therefore,

$$
\left\{\begin{array}{l}
x-a=\left(H_{x}^{\prime}\right)^{\top} q+C t  \tag{31}\\
y-b=\left(H_{y}^{\prime}\right)^{\top} q \\
w-c=\left(H_{w}^{\prime}\right)^{\top} q+A t
\end{array}\right.
$$

Thus, by 29 and (31),

$$
\left[\begin{array}{cc}
H_{x}^{\prime}\left(H_{x}^{\prime}\right)^{\top}+H_{y}^{\prime}\left(H_{y}^{\prime}\right)^{\top}+H_{w}^{\prime}\left(H_{w}^{\prime}\right)^{\top} & H_{x}^{\prime} C+H_{w}^{\prime} A  \tag{32}\\
C\left(H_{x}^{\prime}\right)^{\top}+A\left(H_{w}^{\prime}\right)^{\top} & C^{2}+A^{2}
\end{array}\right]\left[\begin{array}{l}
q \\
t
\end{array}\right]=\left[\begin{array}{c}
-H \\
-C a+\mu
\end{array}\right]
$$

Therefore,

$$
\begin{equation*}
t=-\left(C^{2}+A^{2}\right)^{-1}\left(C\left(H_{x}^{\prime}\right)^{\top}+A\left(H_{w}^{\prime}\right)^{\top}\right) q-\left(C^{2}+A^{2}\right)^{-1}(C a-\mu) \tag{33}
\end{equation*}
$$

By the first equation of 32 and 33 we have that:

$$
\begin{gather*}
\left(\left(H_{x}^{\prime}\left(H_{x}^{\prime}\right)^{\top}+H_{y}^{\prime}\left(H_{y}^{\prime}\right)^{\top}+H_{w}^{\prime}\left(H_{w}^{\prime}\right)^{\top}\right)\right. \\
\left.-\left(H_{x}^{\prime} C+H_{w}^{\prime} A\right)\left(C^{2}+A^{2}\right)^{-1}\left(C\left(H_{x}^{\prime}\right)^{\top}+A\left(H_{w}^{\prime}\right)^{\top}\right)\right) q  \tag{34}\\
=-H+\left(H_{x}^{\prime} C+H_{w}^{\prime} A\right)\left(C^{2}+A^{2}\right)^{-1}(C a-\mu)
\end{gather*}
$$

Note that

$$
\begin{equation*}
\left(C^{2}+A^{2}\right)^{-1}=C^{-1}\left(I+C^{-1} A^{2} C^{-1}\right)^{-1} C^{-1} \tag{35}
\end{equation*}
$$ $\left.A^{2}\right)^{-1}\left(C\left(H_{x}^{\prime}\right)^{\top}+A\left(H_{w}^{\prime}\right)^{\top}\right)$.

Then, by 35,

$$
\begin{align*}
\tilde{H}^{\prime}= & H_{x}^{\prime}\left(H_{x}^{\prime}\right)^{\top}+H_{y}^{\prime}\left(H_{y}^{\prime}\right)^{\top}+H_{w}^{\prime}\left(H_{w}^{\prime}\right)^{\top} \\
& -\left(H_{x}^{\prime}+H_{w}^{\prime} A C^{-1}\right)\left(I+C^{-1} A^{2} C^{-1}\right)^{-1}\left(\left(H_{x}^{\prime}\right)^{\top}+C^{-1} A\left(H_{w}^{\prime}\right)^{\top}\right) \tag{36}
\end{align*}
$$

By $\sqrt[36]{ }$, since $A \rightarrow 0$, we have that $\tilde{H}^{\prime} \rightarrow H_{y}^{\prime}\left(z^{*}\right) H_{y}^{\prime}\left(z^{*}\right)^{\top}+H_{w}^{\prime}\left(z^{*}\right) H_{w}^{\prime}\left(z^{*}\right)^{\top}$.
Since the matrix $\left[\begin{array}{ll}H_{y}^{\prime} & H_{w}^{\prime}\end{array}\right]$ is full row-rank, we have that, if $(a, b, c)$ is close enough to $z^{*}, \tilde{H}^{\prime}$ is nonsingular and its inverse is bounded. Then, recalling that, by (34),

$$
\begin{equation*}
q=\left(\tilde{H}^{\prime}\right)^{-1}\left(-H+\left(H_{x}^{\prime} C+H_{w}^{\prime} A\right)\left(C^{2}+A^{2}\right)^{-1}(C a-\mu)\right) \tag{37}
\end{equation*}
$$

we obtain that $q$ is bounded if $(a, b, c)$ is close enough to the solution and $\mu$ is close enough to 0 . Moreover, since $C a-\mu \rightarrow 0$, we have that $q=q(a, b, c, \mu)$

Let us define $\tilde{H}^{\prime}=H_{x}^{\prime}\left(H_{x}^{\prime}\right)^{\top}+H_{y}^{\prime}\left(H_{y}^{\prime}\right)^{\top}+H_{w}^{\prime}\left(H_{w}^{\prime}\right)^{\top}-\left(H_{x}^{\prime} C+H_{w}^{\prime} A\right)\left(C^{2}+\right.$

Recall that $x-a=\left(H_{x}^{\prime}\right)^{\top} q+C t$. Then, by (33),

$$
\begin{align*}
C t= & -C\left(\left(C^{2}+A^{2}\right)^{-1}\left(C\left(H_{x}^{\prime}\right)^{\top}+A\left(H_{w}^{\prime}\right)^{\top}\right) q-\left(C^{2}+A^{2}\right)^{-1}(C a-\mu)\right) \\
= & -C C^{-1}\left(I+C^{-1} A^{2} C^{-1}\right)^{-1} C^{-1} C\left(\left(H_{x}^{\prime}\right)^{\top}+C^{-1} A\left(H_{w}^{\prime}\right)^{\top}\right) q \\
& -C C^{-1}\left(I+C^{-1} A^{2} C^{-1}\right)^{-1} C^{-1} C\left(a-C^{-1} \mu\right) \\
= & -\left(I+C^{-1} A^{2} C^{-1}\right)^{-1}\left(\left(H_{x}^{\prime}\right)^{\top}+C^{-1} A\left(H_{w}^{\prime}\right)^{\top}\right) q \\
& -\left(I+C^{-1} A^{2} C^{-1}\right)^{-1}\left(a-C^{-1} \mu\right) \tag{40}
\end{align*}
$$

and

$$
\begin{align*}
x= & \left(H_{x}^{\prime}\right)^{\top} q+C t+a \\
= & \left(I-\left(I+C^{-1} A^{2} C^{-1}\right)^{-1}\right) a+\left(I-\left(I+C^{-1} A^{2} C^{-1}\right)^{-1}\right)\left(H_{x}^{\prime}\right)^{\top} q \\
& -\left(I+C^{-1} A^{2} C^{-1}\right)^{-1}\left(C^{-1} A\left(H_{w}^{\prime}\right)^{\top}\right) q+\left(I+C^{-1} A^{2} C^{-1}\right)^{-1} C^{-1} \mu \tag{41}
\end{align*}
$$

Observe that

$$
\begin{aligned}
I-\left(I+C^{-1} A^{2} C^{-1}\right)^{-1} & =I-I-\sum_{j=1}^{\infty}(-1)^{j}\left(C^{-1} A^{2} C^{-1}\right)^{j} \\
& =C^{-1} A^{2} C^{-1}\left(I+\sum_{j=1}^{\infty}(-1)^{j}\left(C^{-1} A^{2} C^{-1}\right)^{j}\right)
\end{aligned}
$$

Then, by 41,

$$
\begin{aligned}
x= & C^{-1} A^{2} C^{-1}\left(I+\sum_{j=1}^{\infty}(-1)^{j}\left(C^{-1} A^{2} C^{-1}\right)^{j}\right) a \\
& +C^{-1} A^{2} C^{-1}\left(I+\sum_{j=1}^{\infty}(-1)^{j}\left(C^{-1} A^{2} C^{-1}\right)^{j}\right)\left(\left(H_{x}^{\prime}\right)^{\top} q\right) \\
& -A C^{-1}\left(I+C^{-1} A^{2} C^{-1}\right)^{-1}\left(\left(H_{w}^{\prime}\right)^{\top}\right) q+\left(I+C^{-1} A^{2} C^{-1}\right)^{-1} C^{-1} \mu .
\end{aligned}
$$

Therefore, for all $i=1, \ldots, n$ we have that

$$
\begin{align*}
x_{i} \geq & \left(c_{i}\right)^{-2}\left(a_{i}\right)^{2}\left[\left(I+\sum_{j=1}^{\infty}(-1)^{j}\left(C^{-1} A^{2} C^{-1}\right)^{j}\right) a\right]_{i} \\
& +\left(c_{i}\right)^{-2}\left(a_{i}\right)^{2}\left[\left(I+\sum_{j=1}^{\infty}(-1)^{j}\left(C^{-1} A^{2} C^{-1}\right)^{j}\right)\left(\left(H_{x}^{\prime}\right)^{\top} q\right)\right]_{i}  \tag{42}\\
& -\left(c_{i}\right)^{-1} a_{i}\left[\left(I+C^{-1} A^{2} C^{-1}\right)^{-1}\left(\left(H_{w}^{\prime}\right)^{\top}\right) q\right]_{i} .
\end{align*}
$$

Our objective now is to investigate the possible values of $\alpha \in[0,1]$ such that

$$
\begin{equation*}
\alpha x_{i}+(1-\alpha) a_{i}=0 \tag{43}
\end{equation*}
$$

or

$$
\begin{equation*}
\alpha w_{i}+(1-\alpha) c_{i}=0 \tag{44}
\end{equation*}
$$

If (44) takes place, then

$$
\begin{equation*}
\alpha=\frac{c_{i}}{c_{i}-w_{i}} \tag{45}
\end{equation*}
$$

But, by (27) and since $w_{i}^{*}>0$, an $\alpha \in[0,1]$ satisfying (45) cannot exist if $\varepsilon$ is small enough.

Therefore, we only need to analyze the values of $\alpha$ that satisfy 43).
By 43, $\alpha=1+\alpha \frac{x_{i}}{a_{i}}$. Then, by 42,

$$
\begin{aligned}
\alpha \geq & 1+\alpha \frac{\left(c_{i}\right)^{-2}\left(a_{i}\right)^{2}}{a_{i}}\left[\left(I+\sum_{j=1}^{\infty}(-1)^{j}\left(C^{-1} A^{2} C^{-1}\right)^{j}\right) a\right]_{i} \\
& +\frac{\left(c_{i}\right)^{-2}\left(a_{i}\right)^{2}}{a_{i}}\left[\left(I+\sum_{j=1}^{\infty}(-1)^{j}\left(C^{-1} A^{2} C^{-1}\right)^{j}\right)\left(\left(H_{x}^{\prime}\right)^{\top} q\right)\right]_{i} \\
& -\frac{\left(c_{i}\right)^{-1} a_{i}}{a_{i}}\left[\left(I+C^{-1} A^{2} C^{-1}\right)^{-1}\left(H_{w}^{\prime}\right)^{\top} q\right]_{i} .
\end{aligned}
$$

Thus,

$$
\begin{align*}
\alpha \geq & 1+\alpha\left(c_{i}\right)^{-2} a_{i}\left[\left(I+\sum_{j=1}^{\infty}(-1)^{j}\left(C^{-1} A^{2} C^{-1}\right)^{j}\right) a\right]_{i} \\
& +\alpha\left(c_{i}\right)^{-2} a_{i}\left[\left(I+\sum_{j=1}^{\infty}(-1)^{j}\left(C^{-1} A^{2} C^{-1}\right)^{j}\right)\left(H_{x}^{\prime}\right)^{\top} q\right]_{i}  \tag{46}\\
& -\alpha c_{i}\left[\left(I+C^{-1} A^{2} C^{-1}\right)^{-1}\left(H_{w}^{\prime}\right)^{\top} q\right]_{i}
\end{align*}
$$

By (38) and 46), given any $\delta \in[0,1)$, and taking $\varepsilon$ small enough we obtain that $\alpha=1$. Consequently, $\alpha_{k}^{\text {break }} \geq \delta$.

### 4.2. Convergence of the whole sequence

Assumption L. For all $z, z^{\prime} \in \Omega$,

$$
\begin{equation*}
\left\|F^{\prime}(z)-F^{\prime}\left(z^{\prime}\right)\right\| \leq L\left\|z^{\prime}-z\right\| \forall z, z^{\prime} \in \Omega \subset \mathbb{R}^{m+2 n} \tag{47}
\end{equation*}
$$

As a consequence, for all $z, z^{\prime} \in \Omega$,

$$
\begin{equation*}
\left\|F\left(z^{\prime}\right)-F(z)-F^{\prime}(z)\left(z^{\prime}-z\right)\right\| \leq \frac{L}{2}\left\|z^{\prime}-z\right\|^{2} \tag{48}
\end{equation*}
$$

Theorem 4. 2 Assume that Assumption $L$ holds, $z^{*} \in \Omega$ is a cluster point of a sequence generated by Algorithm PGUN, $F^{\prime}\left(z^{*}\right)$ is full row-rank and, for $k$ large enough, we choose

$$
\begin{equation*}
z^{k+1}=z^{k}+\alpha_{k} d^{k} \tag{49}
\end{equation*}
$$

at Step 6 of the algorithm. Assume, further, that $c_{\text {big }}$ (used at Step 2 of Algorithm PGUN) is greater than $4\left\|F^{\prime}\left(z^{*}\right)^{\dagger}\right\|$ and $\lim _{k \rightarrow \infty} \tau_{k}=1$. Then, $\lim _{k \longrightarrow \infty} z^{k}=$ $z^{*}$ and

$$
\begin{equation*}
\alpha_{k}=\alpha_{k}^{\max } \tag{50}
\end{equation*}
$$

for $k$ large enough.
Proof. Let $K_{1}$ be an infinite sequence of indices such that $\lim _{k \in K_{1}} z^{k}=z^{*}$. By
Theorem 3.1, $z^{*}$ is a stationary point of $f$ over $\Omega$.
The choice of $d^{k}$ at Step 2 of the algorithm gives:

$$
\begin{equation*}
H^{\prime}\left(z^{k}\right) d^{k}+H\left(z^{k}\right)=0 \tag{51}
\end{equation*}
$$

and

$$
\left(x_{i}^{k}\left[d_{w}^{k}\right]_{i}+w_{i}^{k}\left[d_{x}^{k}\right]_{i}+x_{i}^{k} w_{i}^{k}\right)^{2}=\sigma_{k}^{2} \frac{\left\langle x^{k}, w^{k}\right\rangle^{2}}{n^{2}} \leq \sigma_{k}^{2} \frac{\sum_{i=1}^{n}\left(x_{i}^{k} w_{i}^{k}\right)^{2}}{n}
$$

So,

$$
\sum_{i=1}^{n}\left(x_{i}^{k}\left[d_{w}^{k}\right]_{i}+w_{i}^{k}\left[d_{x}^{k}\right]_{i}+x_{i}^{k} w_{i}^{k}\right)^{2} \leq \sigma_{k}^{2} \sum_{i=1}^{n}\left(x_{i}^{k} w_{i}^{k}\right)^{2} \leq \sigma_{k}^{2}\left\|F\left(z^{k}\right)\right\|^{2}
$$

Then, by (51),

$$
\begin{equation*}
\left\|F^{\prime}\left(z^{k}\right) d^{k}+F\left(z^{k}\right)\right\| \leq \sigma_{k}\left\|F\left(z^{k}\right)\right\| \tag{52}
\end{equation*}
$$

Since $F^{\prime}\left(z^{*}\right)$ is full row-rank, there exists $\varepsilon_{1}>0$ such that $\left\|F^{\prime}(z)^{\dagger}\right\| \leq$ $M_{1} \equiv 2\left\|F^{\prime}\left(z^{*}\right)^{\dagger}\right\|$ and $F^{\prime}(z)$ is full row rank whenever $\left\|z-z^{*}\right\| \leq \varepsilon_{1}$. Moreover, $F^{\prime}(z)^{\dagger} F^{\prime}(z) F^{\prime}(z)^{\dagger}=F^{\prime}(z)^{\dagger}$. Therefore, by 52 , for $k \in K_{1}$ large enough and

$$
\begin{align*}
\left\|z^{k}-z^{*}\right\| & \leq \varepsilon_{1} \\
\left\|d^{k}\right\| & =\left\|F^{\prime}\left(z^{k}\right)^{\dagger}\left[\begin{array}{c}
-H\left(z^{k}\right) \\
-X_{k} W_{k} e+\mu^{k}
\end{array}\right]\right\| \\
& =\left\|F^{\prime}\left(z^{k}\right)^{\dagger} F^{\prime}\left(z^{k}\right) F^{\prime}\left(z^{k}\right)^{\dagger}\left[\begin{array}{c}
-H\left(z^{k}\right) \\
-X_{k} W_{k} e+\mu^{k}
\end{array}\right]\right\| \\
& =\left\|F^{\prime}\left(z^{k}\right)^{\dagger} F^{\prime}\left(z^{k}\right) d^{k}\right\| \leq\left\|F^{\prime}\left(z^{k}\right)^{\dagger}\right\|\left\|F^{\prime}\left(z^{k}\right) d^{k}+F\left(z^{k}\right)-F\left(z^{k}\right)\right\| \\
& \leq\left\|F^{\prime}\left(z^{k}\right)^{\dagger}\right\|\left(\left\|F^{\prime}\left(z^{k}\right) d^{k}+F\left(z^{k}\right)\right\|+\left\|F\left(z^{k}\right)\right\|\right) \leq M_{1}\left(1+\sigma_{k}\right)\left\|F\left(z^{k}\right)\right\| . \tag{53}
\end{align*}
$$

By Theorem3.1, we have that $F\left(z^{*}\right)=0$. Moreover, since $c_{b i g} \geq 4\left\|F^{\prime}\left(z^{*}\right)^{\dagger}\right\|$, if $\left\|z^{k}-z^{*}\right\| \leq \varepsilon_{1}, k \in K_{1}$, large enough, we have that $\left\|F\left(z^{k}\right)\right\| \leq 1$ and 53 . implies that $d^{k}$ is computed at Step 2.

Define $M_{2}=2\left\|F^{\prime}\left(z^{*}\right)\right\|$. Then, since $F$ and $F^{\prime}$ are continuous, $F\left(z^{*}\right)=0$.
235 By (53) and Theorem 41 there exists $\varepsilon_{2} \in\left(0, \varepsilon_{1}\right]$ such that for all $k \in \mathbb{N}$ such that $\left\|z^{k}-z^{*}\right\| \leq \varepsilon_{2}$, we have that:
(i) $\left\|d^{k}\right\| \leq M_{1}\left(1+\sigma_{k}\right)\left\|F\left(z^{k}\right)\right\|$;
(ii) $\alpha_{k}^{\max } \geq \max \left\{1-\frac{1}{12 M_{1} M_{2}}, \frac{11}{12}\right\}$;
(iii) $\left\|F^{\prime}\left(z^{k}\right)\right\| \leq M_{2}$;

240 (iv) $\left\|F\left(z^{k}\right)\right\| \leq \frac{1}{12 L M_{1}^{2}}$;
(v) $\rho\left\|\alpha_{k}^{\max } d^{k}\right\|^{2} \leq \frac{1}{2}\left\|F\left(z^{k}\right)\right\|$.

Then, for all $k \in \mathbb{N}$ such that $\left\|z^{k}-z^{*}\right\| \leq \varepsilon_{2}$,

$$
\begin{align*}
& \left\|F\left(z^{k}+\alpha_{k}^{\text {max }} d^{k}\right)\right\| \\
& \leq\left\|F\left(z^{k}+\alpha_{k}^{\max } d^{k}\right)-F\left(z^{k}\right)-\alpha_{k}^{\max } F^{\prime}\left(z^{k}\right) d^{k}\right\|+\left\|F\left(z^{k}\right)+\alpha_{k}^{\max } F^{\prime}\left(z^{k}\right) d^{k}\right\| \\
& \leq \frac{L}{2}\left(\alpha_{k}^{\max }\right)^{2}\left\|d^{k}\right\|^{2}+\left\|F\left(z^{k}\right)+F^{\prime}\left(z^{k}\right) d^{k}\right\|+\left(1-\alpha_{k}^{\max }\right)\left\|F^{\prime}\left(z^{k}\right) d^{k}\right\| \\
& \leq \frac{L}{2}\left(\alpha_{k}^{\max }\right)^{2}\left\|d^{k}\right\|^{2}+\sigma_{k}\left\|F\left(z^{k}\right)\right\|+\left(1-\alpha_{k}^{\max }\right)\left\|F^{\prime}\left(z^{k}\right) d^{k}\right\| \\
& \leq \frac{L}{2}\left(\alpha_{k}^{\max }\right)^{2} M_{1}^{2}\left(1+\sigma_{k}\right)^{2}\left\|F z^{k}\right\|^{2}+\sigma_{k}\left\|F\left(z^{k}\right)\right\| \\
& \quad+\left(1-\alpha_{k}^{\max }\right)\left\|F^{\prime}\left(z^{k}\right)\right\| M_{1}\left(1+\sigma_{k}\right)\left\|F z^{k}\right\| \\
& \leq\left(\frac{L}{2}\left(\alpha_{k}^{\max }\right)^{2} M_{1}^{2}\left\|F\left(z^{k}\right)\right\|+\sigma_{k}+\left(1-\alpha_{k}^{\max }\right)\left(1+\sigma_{k}\right) M_{2} M_{1}\right)\left\|F\left(z^{k}\right)\right\| \\
& \leq \frac{1}{2}\left\|F\left(z^{k}\right)\right\| \leq\left\|F\left(z^{k}\right)\right\|-\rho\left\|\alpha_{k}^{\max } d^{k}\right\|^{2}+\gamma_{k} . \tag{54}
\end{align*}
$$

Therefore, by $\sqrt[22]{2}$, for all $k \in I N$ such that $\left\|z^{k}-z^{*}\right\| \leq \varepsilon_{2}$, we have that $\alpha_{k}=\alpha_{k}^{\max }($ proving (50) $)$,

$$
\begin{equation*}
z^{k+1}=z^{k}+\alpha_{k}^{\max } d^{k}, \quad \text { and } \quad\left\|F\left(z^{k+1}\right)\right\| \leq \frac{1}{2}\left\|F\left(z^{k}\right)\right\| \tag{55}
\end{equation*}
$$

Since $\lim _{k \in K_{1}} F\left(z^{k}\right)=F\left(z^{*}\right)=0$, there exists $k_{0} \in K_{1}$ such that $\| z^{k_{0}}-$ $z^{*} \| \leq \frac{\varepsilon_{2}}{4}$ and $\left\|F\left(z^{k_{0}}\right)\right\| \leq \frac{\varepsilon_{2}}{4\left(4 M_{1}+1\right)}$. We will prove by induction that $\left\|z^{k}-z^{*}\right\| \leq$ $\varepsilon_{2}$ for all $k \geq k_{0}, k \in \mathbb{N}$. This is trivial for $k=k_{0}$.

Assume, by inductive hypothesis, that $\left\|z^{k}-z^{*}\right\| \leq \varepsilon_{2}$ for all $k=k_{0}, k_{0}+$ $1, \ldots, k_{0}+j-1$. Then, by 55, $\left\|F\left(z^{k+1}\right)\right\| \leq \frac{1}{2}\left\|F\left(z^{k}\right)\right\|$ for $k=k_{0}+1, \ldots, k_{0}+$ $j-1$.

By 55 and (i)-(v), we can write:

$$
\begin{aligned}
\left\|z^{k_{0}+j}-z^{k_{0}}\right\| & =\left\|\sum_{i=0}^{j-1} \alpha_{k_{0}+i}^{\max } d^{k_{0}+i}\right\| \leq 2 M_{1} \sum_{i=0}^{j-1}\left(\frac{1}{2}\right)^{i}\left\|F\left(z^{k_{0}}\right)\right\| \\
& \leq 4 M_{1}\left\|F\left(z^{k_{0}}\right)\right\| \leq \frac{\varepsilon_{2}}{4}
\end{aligned}
$$

Therefore, $\left\|z^{k_{0}+j}-z^{*}\right\| \leq\left\|z^{k_{0}+j}-z^{k_{0}}\right\|+\left\|z^{k_{0}}-z^{*}\right\| \leq \frac{\varepsilon_{2}}{2}$. Thus, $\left\|z^{k_{0}+j}-z^{*}\right\| \leq$ $\varepsilon_{2}$. This completes the inductive proof.

Let us prove now that $\left\{z^{k}\right\}$ is a Cauchy sequence.
Let $j \geq k_{0}$ and $\ell \geq 1$. Then,

$$
\begin{align*}
\left\|z^{j+\ell}-z^{j}\right\| & \leq \sum_{i=0}^{\ell-1} \alpha_{j+i}^{\max }\left\|d^{j+i}\right\| \\
& \leq 2 M_{1} \sum_{i=0}^{\ell-1}\left(\frac{1}{2}\right)^{i+1}\left\|F\left(z^{j}\right)\right\|  \tag{56}\\
& \leq 2 M_{1} \sum_{i=0}^{\ell-1}\left(\frac{1}{2}\right)^{i+1}\left\|F\left(z^{j}\right)\right\| \leq 2 M_{1}\left\|F\left(z^{j}\right)\right\|
\end{align*}
$$

Since $\lim _{j \rightarrow \infty}\left\|F\left(z^{j}\right)\right\|=0$, 56 implies that $\left\{z^{k}\right\}$ is a Cauchy sequence. Then, since $z^{*}$ is a limit point, we have that $\lim _{k \longrightarrow \infty} z^{k}=z^{*}$.

### 4.3. Superlinear and quadratic convergence

In this section we will prove that, under the assumptions of Theorem 4.2 and adequate choices of the parameters $\sigma_{k}$, the algorithm exhibits superlinear or quadratic convergence.

We will consider the following assumption on the parameters $\sigma_{k}$.

Assumption S. Choose $\sigma_{k}$ such that

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \sigma_{k}=0 \tag{57}
\end{equation*}
$$

Theorem 4.3. Assume that $\left\{z^{k}\right\}$ is generated by Algorithm PGUN and converges to $z^{*}$ such that $F\left(z^{*}\right)=0$, where $F^{\prime}\left(z^{*}\right)$ is full row-rank, and for $k$ large enough we choose

$$
\begin{equation*}
z^{k+1}=z^{k}+\alpha_{k} d^{k} \tag{58}
\end{equation*}
$$

260 at Step 6 of the algorithm. Assume that the hypotheses of Theorem 4.2, and both assumptions $L$ and $S$ hold. Then, $z^{k}$ converges superlinearly to $z^{*}$.

Moreover, if there exists $c_{1}, c_{2}>0$ such that, for all $k$ large enough,

$$
\begin{equation*}
\sigma_{k} \leq c_{1}\left\|F\left(z^{k}\right)\right\| \text { and } 1-\tau_{k} \leq c_{2}\left\|F\left(z^{k}\right)\right\| \tag{59}
\end{equation*}
$$

$z^{k}$ converges quadratically to $z^{*}$.

Proof. Since $\tau_{k} \rightarrow 1$ we have that $\lim _{k \rightarrow \infty} \alpha_{k}^{\max }=1$.
By Theorem 4. 2 , for all $k$ large enough there exists $M>0$ such that $\left\|d^{k}\right\| \leq$ $M\left\|F\left(z^{k}\right)\right\|,\left\|F^{\prime}\left(z^{k}\right)\right\| \leq M$ and

$$
\begin{align*}
\left\|F\left(z^{k+1}\right)\right\| & \leq\left\|F\left(z^{k+1}\right)-F\left(z^{k}\right)-\alpha_{k}^{\max } F^{\prime}\left(z^{k}\right) d^{k}\right\|+\left\|F\left(z^{k}\right)+\alpha_{k}^{\max } F^{\prime}\left(z^{k}\right) d^{k}\right\| \\
& \leq \frac{L}{2}\left(\alpha_{k}^{\max }\right)^{2}\left\|d^{k}\right\|^{2}+\left\|F\left(z^{k}\right)+F^{\prime}\left(z^{k}\right) d^{k}\right\|+\left(1-\alpha_{k}^{\max }\right)\left\|F^{\prime}\left(z^{k}\right) d^{k}\right\| \\
& \leq \frac{L}{2} M^{2}\left\|F\left(z^{k}\right)\right\|^{2}+\sigma_{k}\left\|F\left(z^{k}\right)\right\|+\left(1-\alpha_{k}^{\max }\right) M^{2}\left\|F\left(z^{k}\right)\right\| \\
& \leq\left(\frac{L}{2} M^{2}\left\|F\left(z^{k}\right)\right\|+\sigma_{k}+\left(1-\alpha_{k}^{\max }\right) M^{2}\right)\left\|F\left(z^{k}\right)\right\|=R_{k}\left\|F\left(z^{k}\right)\right\| \tag{60}
\end{align*}
$$

where $R_{k}=\frac{L}{2} M^{2}\left\|F\left(z^{k}\right)\right\|+\sigma_{k}+M^{2}\left(1-\alpha_{k}^{\max }\right)$. Moreover,

$$
\left\|z^{k+1}-z^{*}\right\| \leq \sum_{j=k+1}^{\infty} \alpha_{j}^{\max }\left\|d^{j}\right\| \leq 2 M \sum_{j=1}^{\infty}\left(\frac{1}{2}\right)^{j}\left\|F\left(z^{k+1}\right)\right\|
$$

By (60) and (48) we have that

$$
\begin{aligned}
\left\|z^{k+1}-z^{*}\right\| & \leq 2 M R_{k}\left\|F\left(z^{k}\right)\right\| \\
& =2 M R_{k}\left\|F\left(z^{k}\right)-F\left(z^{*}\right)-F^{\prime}\left(z^{k}\right)\left(z^{k}-z^{*}\right)+F^{\prime}\left(z^{k}\right)\left(z^{k}-z^{*}\right)\right\| \\
& \leq 2 M R_{k}\left\|F\left(z^{k}\right)-F\left(z^{*}\right)-F^{\prime}\left(z^{k}\right)\left(z^{k}-z^{*}\right)\right\|+\left\|F^{\prime}\left(z^{k}\right)\left(z^{k}-z^{*}\right)\right\| \\
& \leq 2 M R_{k}\left(\frac{L}{2}\left\|z^{k}-z^{*}\right\|+M\right)\left\|z^{k}-z^{*}\right\| \\
& \leq 2 M R_{k} L\left(\frac{L}{2}+M\right)\left\|z^{k}-z^{*}\right\|
\end{aligned}
$$

Since $\lim _{k \rightarrow \infty} R_{k}=0, z^{k}$ converges superlinearly to $z^{*}$.
Now, taking $c=\max \left\{c_{1}, c_{2}\right\}$, since $\max \left\{\sigma_{k}, 1-\alpha_{k}^{\max }\right\} \leq \max \left\{\sigma_{k}, 1-\tau_{k}\right\} \leq$ $c\left\|F\left(z_{k}\right)\right\|$, we have that

$$
\begin{aligned}
\left\|z^{k+1}-z^{*}\right\| & \leq 2 M\left(\frac{L}{2} M^{2}\left\|F\left(z^{k}\right)\right\|+\sigma_{k}+\left(1-\alpha_{k}^{\max }\right) M^{2}\right)\left\|F\left(z^{k}\right)\right\| \\
& \leq 2 M\left(\frac{L}{2} M^{2}+\left(1+M^{2}\right) c\right)\left\|F\left(z^{k}\right)\right\|^{2} \\
& \leq 2 M\left(\frac{L}{2}+M\right)^{2}\left(\frac{L}{2} M^{2}+\left(1+M^{2}\right) c\right)\left\|z^{k}-z^{*}\right\|^{2} .
\end{aligned}
$$

Therefore, quadratic convergence is proved.

## 5. Computational Experience

In this section we will report some experiments with the PGUN algorithm for the solution of (3) and (5). In order to have a better idea of the efficiency of PGUN in practice, we have compared the PGUN method with the ProjectedGradient Levenberg-Marquardt (PLM) algorithm [27.

### 5.1. The Projected Levenberg-Marquardt Algorithm

The Projected Levenberg-Marquardt (PLM) is an algorithm for the solution of constrained nonlinear systems $F(z)=0, z \in Z$, where $Z \in \mathbb{R}^{n}$ is a nonempty, closed and convex set. For solving this problem the method is applied to a nonlinear program of a form similar to where the merit function is also defined by 9 .

The PLM algorithm generates a sequence $\left\{z^{k}\right\}$ by

$$
z^{k+1}=P_{Z}\left(z^{k}+d_{U}^{k}\right) \quad k=0,1, \ldots
$$

where $d_{U}^{k}$ is the unique solution of the system of linear equations

$$
\begin{equation*}
\left(J_{k}^{\top} J_{k}+\mu_{k} I\right) d_{U}=-J_{k}^{\top} F\left(z^{k}\right) \tag{61}
\end{equation*}
$$

and $J_{k}$ is an approximation to the Jacobian $F^{\prime}\left(z^{k}\right)$.

Step 0: Initial setup: Choose $z^{0} \in Z, \mu>0, \beta, \sigma, \gamma \in(0,1), \rho>0$ and $p>1$.
Step 1: Declare finite convergence: If $F\left(z^{k}\right)=0$, stop.
Step 2: Unconstrained direction: Choose $J_{k}$, set $\mu_{k}=\mu\left\|F\left(z^{k}\right)\right\|^{2}$ and compute $d_{U}^{k}$ as the solution of 61.

Step 3: Levenberg-Marquardt step: If

$$
\begin{equation*}
\left\|F\left(P_{Z}\left(z^{k}+d_{U}^{k}\right)\right)\right\| \leqslant \gamma\left\|F\left(z^{k}\right)\right\| \tag{62}
\end{equation*}
$$

Step 4: Line Search step: If the search direction $s^{k}=P_{Z}\left(z^{k}+d_{U}^{k}\right)-z^{k}$ is a descent direction of $f$ in the sense that $\nabla f\left(z^{k}\right)^{\top} s^{k} \leqslant-\rho\left\|s^{k}\right\|^{p}$, set $\alpha=1$ and

Step 4.1: If

$$
\left\|F\left(z^{k}+t s^{k}\right)\right\|^{2} \leqslant\left\|F\left(z^{k}\right)\right\|^{2}+\gamma \alpha \nabla f\left(z^{k}\right)^{\top} s^{k}
$$

then set $z^{k+1}=z^{k}+\alpha s^{k}$ and go to Step 1.

Step 5: Projected Gradient step: Compute a stepsize $\alpha_{k}=\max \left\{\beta^{l} \mid l=\right.$ $0,1,2, \ldots\}$ such that

$$
f\left(z^{k}\left(\alpha_{k}\right)\right) \leqslant f\left(z^{k}\right)+\sigma \nabla f\left(z^{k}\right)^{\top}\left(z^{k}\left(\alpha_{k}\right)-z^{k}\right)
$$

where $z^{k}(\alpha)=P_{Z}\left(z^{k}-\alpha \nabla f\left(z^{k}\right)\right)$. Set $z^{k+1}=z^{k}\left(\alpha_{k}\right)$ and go to Step 1.

### 5.2. Implementation issues and test problems

The codes for the PGUN and PLM algorithms were written in Fortran 77 with double precision and the experiments were performed using gfortarn-4.6 on an Intel CORE I3-2310M@2.10 GHz with 100 Gb of HD and 4 Gb of Ram. Furthermore we used the ma48 routine of the Harwell Subroutine Library [21] for the solution of the linear systems required by the two algorithms.

We considered the following stopping criteria:

SC1: Stop with $z^{k}$ if $\left\|g\left(z^{k}, \eta\right)\right\|<10^{-5}$.

SC2: Stop with $z^{k}$ when SC1 is satisfied and $\left\|F\left(z^{k}\right)\right\|<10^{-6}$.
SC3: Stop at iteration $k$ if $\left\|F\left(z^{k}\right)\right\|>10^{-3}$ and $\left\|F\left(z^{k-1}\right)\right\|-\left\|F\left(z^{k}\right)\right\|<$ $10^{-4}$.

PGUN stops if SC1 occurs at a projected gradient iteration. However, if SC1 takes place at a interior point Newton-like (IP) iteration we continue the execution with the hope of satisfying SC2. If, during this process, a projected gradient iteration is required, we stop with the diagnostic SC1.

In some cases the PGUN algorithm converges very slowly using projectedgradient (PG) iterations to a stationary point with a positive value of the merit function. In this case, PGUN is not converging to a solution of the HNCP and 5 there is no reason to continue the execution of the algorithm. To avoid this occurrence, we decided to stop prematurely the algorithm by using the third
stopping criterion. Moreover, when SC3 occurs the algorithm is restarted with a new initial point.

PLM employs fast Levenberg-Marquardt (LM) and slow Projected-Gradient

$$
\begin{equation*}
x^{0}=e, y^{0}=0, w^{0}=e \tag{63}
\end{equation*}
$$

where $e$ is a vector of ones. The following values for the algorithmic parameters of PGUN were used: $\alpha_{\text {min }}=10^{-8}, \beta=0.25, c_{\text {big }}=10^{4}, c_{\text {small }}=10^{-10}$, $\eta_{k}=\eta=1.0, \gamma_{k}=\frac{1}{k^{2}}, \rho=10^{-3}, \sigma_{k}=\sigma=\frac{1}{\sqrt{2 n+m}}, \tau_{k}=\tau=0.9995$ and $\theta=0.5$. For the PLM Method we utilized the default parameters of [27]: $\alpha_{\text {min }}=10^{-12}, \beta=0.9, \mu=10^{-5}, \sigma=10^{-4}, \gamma=0.99995, p=2.1$ and $\rho=10^{-8}$.

We have made the experiments with both the algorithms on the solution of 48 MPCC test problems of the collection MacMPEC [29]. These problems are presented in Table 1. In this table, m is the dimension of $y, \mathrm{n}$ is the dimension of $x$ and $w, \mathrm{p}$ is the dimension of $(\varphi(x, y, w), H(x, y, w))^{\top}, \mathrm{nz}$ is the number of possible non zero elements of the Jacobian matrix, density is the density of the Jacobian matrix and $\min$ is the lower value known for the function.

### 5.3. Experiment 1: Computing a Simple Feasible Solution of MPCC

In order to compute a simple feasible solution of the MPCC, we considered the HNCP of the form (3). Table 2 shows the number of complementary pairs for each problem. In this table, NCP represents the number of original complementary pairs and NNG is the number of complementary pairs after each nonnegative non-complementary variable $x_{i}$ is transformed into a pair of complementary variables $\left(x_{i}, w_{i}\right)$ with $w_{i}$ an auxiliary variable.

Table 3 reports the performance of the PGUN algorithm for finding a sim-

ple feasible solution of the Mathematical Program with Complementarity Con- straints (MPCC). In this table, we use the following notations:

TERM: termination of the algorithm which can be one of the following:

IP-1: algorithm stopped with an interior-point Newton-like (IP) iteration satisfying SC1.

IP-2: algorithm stopped with an IP iteration satisfying SC2.
PG-1: algorithm stopped with a projected-gradient (PG) iteration satisfying SC1.

IP: number of interior-point Newton-like (IP) iterations.

PG: number of projected-gradient (PG) iterations.

Table 2: Number of complementary pairs for Experiment 1

| Problem | NCP | NNG | Problem | NCP | NNG | Problem | NCP |
| :--- | :---: | :---: | :--- | :--- | :--- | :--- | :--- |

CG: number of times that the algorithm changed from an IP to a PG iteration or conversely.

NE: number of function evaluations.

TIME: CPU time (in seconds), measured with the function etime. A time smaller than 1e-4 is considered as zero.
$\|F(\bar{z})\|$ : value of $\|F(\bar{z})\|$, where $\bar{z}$ is the solution computed by the algorithm.

SPG_norm: norm of the projected-gradient at the solution computed by the algorithm.

Feas: feasibility measure, that is, Feas $=\|h(\bar{z})\|$.
Comp: complementarity measure, that is, $\operatorname{Comp}=\max _{i=1, n}\left\{x_{i} w_{i}\right\}$.

* The algorithm computed a feasible solution of MPCC with an initial point different from 63.
** failure: The algorithm was not able to compute a feasible solution of MPCC after 10 trials with different starting points.

Table 3: Performance of the PGUN method for Experiment 1

The performance of the PGUN algorithm for finding a simple feasible solution of the 48 MPCCs is illustrated in Table 3. These results indicate that in general the algorithm converged fast to a solution of HNCP, as it performed a small number of IP iterations. In fact, there was only one case in which PGUN required too many IP iterations and only 2 instances where the algorithm required 2 slow PG iterations. For 3 instances the stopping criterion SC3 was
merit function that would not be a solution of HNCP. In these 3 cases PGUN converged to a solution of HNCP by using an alternative starting point. Finally, the algorithm was unable to find a feasible solution of the MPCC in two instances.

We also note from the values of Feas and Comp that PGUN is usually able to compute accurate feasible solutions of the MPCC. Furthermore, the use of the stopping criterion SC2 was shown appropriate for such a goal. This is an interesting point as these accurate solutions can be used as initial points for projected and active-set algorithms [11, 16, 26, 38] that have been designed for the computation of stationary points of MPCC.

In order to have a better idea of the performance of PGUN in practice, we also solved the test problems by the PLM algorithm. The results of the performance of this method are displayed in Table 4, where the notations mentioned before were used together with the following additional ones:

TERM: algorithm termination, which can be one of the following:

LM-1: algorithm stopped with a Levenberg-Marquardt (LM) iteration satisfying SC1.

LM-2: algorithm stopped with a LM iteration satisfying SC2.
PG-1: algorithm stopped with a projected gradient (PG) iteration satisfying SC1.

LM: number of LM iterations (steps 2,3 and 4 ).

PG: number of PG iterations (step 5).

The numerical results indicate that the PLM algorithm used a small number of fast LM iterations to converge and rarely employs slow PG iterations. As before, the stopping criterion SC3 was used in order to stop prematurely the convergence to points that are not feasible solutions of MPCC. As for the PGUN algorithm the use of the stopping criterion SC2 usually leads to accurate feasible solutions of MPCC (see values in the columns Comp and Feas). Finally, the

PLM method seems to have more failures for finding a feasible solution than the PGUN algorithm. This leads to our recommendation of using PGUN for computing a feasible solution of an MPCC.

### 5.4. Experiment 2: Computing a Target Feasible Solution of MPCC

Next, we report the experiments with PGUN and PLM for computing a target feasible solution (i.e., a solution of HNCP (5)) of the MPCC test problems mentioned before when the target value $c_{t}$ is the best value given by the collection. The definition of the test problems used in this experiment and the numerical results on the performance of the algorithms for these instances are
displayed in Table 5 and Tables 6 and 7, respectively. In these tables we used the notations mentioned before and the additional one:

SLACK: represents the value of the slack variable associated to the target constraint. If SLACK is greater than a tolerance $10^{-6}$, then the algorithm was able to compute a better feasible solution than the one given by the collection.

Table 5: Number of complementary pairs for Experiment 2

| Problem | NCP | NNG | Problem | NCP | NNG | Problem | NCP |
| :--- | :---: | :---: | :--- | :--- | :--- | :--- | :--- |

The numerical results indicate the same type of performance shown before. However, there is an increase of failures of the algorithms when the objective function constraint is included in the HNCP associated to a target feasible solution. Furthermore PGUN and PLM always computed the feasible solution given by the collection (see values in the column SLACK). These conclusions confirm the conclusions in [12] that computing a target feasible solution is usually more difficult than finding a simple feasible solution.

## 6. Conclusions

In this paper, we introduced a Projected-Gradient Underdetermined Newtonlike (PGUN) algorithm for computing a feasible solution of a Mathematical Programming Problem with Complementarity Constraints (MPCC). The algorithm can also be applied for the computation of a feasible solution of MPCC that satisfies a certain objective function target. In both cases the algorithm searches a solution of an associated Horizontal Complementarity Problem (HNCP). It was shown that PGUN is globally convergent to a solution of HNCP or to a stationary point of an associated natural merit function. Fast local convergence was established under reasonable hypotheses. The PGUN algorithm seems to perform well for the computation of feasible solutions of an MPCC and seems

to be more efficient than a Projected Levenberg-Marquardt (PLM) algorithm designed before for the same goal. The choice of the initial point for the PGUN and PLM algorithms seems to have an important impact on the efficiency of these algorithms. Future research will address the combination of PGUN with algorithms that require feasible initial points for solving MPCC in order to solve practical problems.

## 7. Acknowledgement

We are indebted to the associate editor and two anonymous referees for helpful remarks that improved a lot the quality of this paper.
